ABSTRACT:

PURPOSE: To realize a transmission type screen having good image quality without causing moire by specifying the lens pitch of a lenticular lens part and the lens pitch of a Fresnel lens part.

CONSTITUTION: The transmission type screen 2 is constituted of a Fresnel lens sheet 21, a lenticular lens sheet 22, and the pitch P3 of the lenticular lens 22 is formed so that it may be smaller than 1/3.3 fold one of the pitch P1 of a projection frame or so that it may be 1/2.35-1/2.65 fold one or 1/1.35-1/1.65 fold or 1.35-1.45 fold one of the pitch P1. Then, the lens pitch P3 of the Fresnel lens 21 is made smaller than 1/3.3 fold one of the

pitch P1 of a
picture element frame. Thus, the concentric fringe of the
shadow of the
picture element frame and the Fresnel lens does not
interfere with the vertical
fringe of the lenticular lens and the moire does not occur
at the time of
projecting an image on the screen 2 by a liquid crystal
projector 1.

ABSTRACT:

PURPOSE: To suppress intervals of Moire fringis less than a picture element and to prevent the deterioration of picture quality by making pitch of a unidimensional lens less than a half of equivalent pitch.

CONSTITUTION: A luminous flux from a light source 1 is condensed by a condenser 2 and image information is given by a matrix type light bulb. A Fresnel lens face 6 that acts as a convex lens as a whole and a lenticular lens face 7 having pitch less than 1/2 of projection picture element pitch which is a unidimensional lens are formed in a screen 5. As the ratio of the pitch of the lenticular lens and that of projection picture element is made to 0.27, the pitch of Moire fringis becomes smaller than the pitch of projection picture

element, and deterioration of picture quality is not
observed in actual visual
perception.
